Chapter 1

INTRODUCTION TO GROUP THEORY

1.1 Set Theory

July 22nd.

We begin with some basic assumptions to introduce set theory. The symbol \in is used to denote membership in a set. A statement using this in set theory may be stated as $x \in y$, which can be either true or false. Once we have developed this language to discuss sets, we can introduce some axioms.

Axiom 1.1. There exists a set with no elements, the *empty set* \emptyset .

Formally, the above axiom is $\exists x(\forall y(y \notin x))$.

Axiom 1.2. Two sets are equal if they have the same elements.

From the above two axioms, we can infer a unique empty set. A notion of subsets may also be declared.

Definition 1.3. We say the set A is a *subset* of the set B , denoted $A \subseteq B$, if every element of A is also an element of B .

We also have a bunch of similarity axioms stated below.

Axiom 1.4 (Similarity axioms). We have the following:

1. If x, y are sets, then $\{x, y\} \Rightarrow \{x, \{x, y\}\}$ (not an ordered pair).
2. If A is a set, then $\bigcup A = \{x \mid \exists y \in A, x \in y\}$ is a set.
3. There exists a *power set* for every set; given a set A , there exists a set $P(A)$ such that for all $B \subseteq A$, $B \in P(A)$. Formally, $\forall A \exists P(A)(\forall B \subseteq A, B \in P(A))$.
4. The *infinite axiom*: Formally, $\exists I(\emptyset \in I \wedge \forall y \in I(P(y) \in I))$.
5. If A and B are sets, then $A \times B = \{(x, y) \mid x \in A, y \in B\}$ is a set.

Before discussing the last axiom, we define a relation on sets.

Definition 1.5. A *relation* R on a set A is a subset $R \subseteq A \times A$. If $(x, y) \in R$, we write xRy .

Axiom 1.6 (The *axiom of choice*). Let A be a collection of non-empty and disjoint sets. Then there exists a set C consisting of exactly one element from each set in A .

Definition 1.7. A relation R on a set A is said to be:

- *reflexive* if $xRx \forall x \in A$,
- *symmetric* if $xRy \Rightarrow yRx$,
- *transitive* if $xRy \wedge yRz \Rightarrow xRz$,
- *antisymmetric* if $xRy \wedge yRx \Rightarrow x = y$.

Definition 1.8. A *partial order* on a set A is a reflexive, transitive, and antisymmetric relation on A .

Some examples of partially ordered sets include (R, \leq) , $(P(\mathbb{R}), \subseteq)$.

Definition 1.9. A *total order* R on a set A is a partial order such that for all $x, y \in A$, either xRy or yRx .

Again, (R, \leq) is a totally ordered set, but not $(P(\mathbb{R}), \subseteq)$.

Definition 1.10. A total order \leq on a set A is said to be a *well-order* if given any non-empty subset $B \subseteq A$, there exists $x \in B$ such that for all $y \in B$, $x \leq y$.

The below theorem may be derived from the above definitions and axioms.

Theorem 1.11 (The *well-ordering principle*). *Every set can be well-ordered.*

We may note that the well-ordering principle and the axiom of choice are equivalent.

Definition 1.12. A *chain* in partially ordered set A , with relation \prec , is a subset of A which is totally ordered with respect to \prec .

Definition 1.13. Let $C \subseteq A$ be a subset in a partially ordered set (A, \prec) . An element $x \in A$ is an *upper bound* of C if for all $y \in C$, $y \prec x$.

Definition 1.14. An element $x \in A$ is a *maximal element* of a partially ordered set (A, \prec) if for all $y \in A$, $x \prec y \Rightarrow x = y$.

Lemma 1.15 (Zorn's lemma). *Let A be a set and let \prec be a partial order on A such that every chain in A has an upper bound. Then A has a maximal element.*

Theorem 1.16. *The following are equivalent:*

1. *The axiom of choice,*
2. *The well-ordering principle,*
3. *Zorn's lemma.*

Proof. We begin with 2. implies 3.; let A be a non-empty set. Consider

$$\mathcal{C} = \{(B, \leq) \mid B \subseteq A \text{ and } \leq \text{ is a well-order on } B\}. \quad (1.1)$$

We note that \mathcal{C} is non-empty since if we pick $B = \{x\}$ for some $x \in A$, then $x \leq x$ and $(B, \leq) \in \mathcal{C}$. Let $(B, \leq), (C, \leq') \in \mathcal{C}$. We say $(B, \leq) \preceq (C, \leq')$ if there exists $y \in C$ such that

$$B = \{x \in C \mid x \leq' y\} (= I(c, y)) \text{ and } \leq = \leq'|_B, \text{ or } (B, \leq) = (C, \leq') \quad (1.2)$$

Note that \preceq is a partial order on \mathcal{C} and is clearly reflexive.

For transitivity, if we take $B \preceq C$ and $C \preceq D$, then $B = C$ or $B = I(C, y)$ for some $y \in C$, and $C = D$ or $C = I(D, z)$ for some $z \in D$. If equality holds in either case, then clearly $B \preceq D$. If $B = I(C, y)$ and $C = I(D, z)$. Clearly, $B = I(D, y)$.

Now let $T = (\{(B_i, \leq_i) \mid i \in I\})$ be a chain in \mathcal{C} . Let $B = \bigcup_{i \in I} B_i$, and $\leq = \bigcup_{i \in I} \leq_i$. Note that this makes sense since if $x \in B_i$ and $y \in B_j$ with $B_i \preceq B_j$, then $x, y \in B_j$. So, we assign $x \leq y$ if $x \leq_j y$. Now let $C \subseteq B$ be non-empty. Also let $x \in C$; then $x \in B_i$ for some $i \in I$. Let $w = \min(B_i \cap C)$. We claim that $w = \min C$. For $y \in C$, if $y \in B_i$ then $w \leq y$. If $y \notin B_i$ then $y \in B_j \in T$. Since T is a chain, either $B_i \preceq B_j$ or $B_j \preceq B_i$; the latter is not possible since $y \notin B_i$. Thus, $B_i = I(B_j, z)$, for some $z \in B_j$, and for any $x \in B_i$, $w \leq x \leq y$.

So $(B, \leq) \in \mathcal{C}$ and it is an upper bound of T ; to realize it is an upper bound, we show that $B_i \preceq B$ for all valid i . If $B_i = B$, we are done. Otherwise, let $x = \min(B \setminus B_i)$. Then $B_i = I(B, x)$, and $B_i \preceq B$. Thus, by Zorn's lemma, \mathcal{C} has a maximal element—call it (M, \leq) .

We now claim that $M = A$. If $M \subsetneq A$, then let $a \in A \setminus M$. If we let $\hat{M} = (M \cup \{a\}, \leq')$ where $x \leq' a$ for all $x \in M$, then $M = I(\hat{M}, a)$ but this is a contradiction to the fact that (M, \leq) is a maximal element. Thus, $A = M$.

Next comes 1. implies 3. Let X be a partially ordered set such that every chain has an upper bound. Suppose X has no maximal element; we will utilise the axiom of choice to arise at a contradiction. For every chain T in X , there exists a strict upper bound c_T . Define a function f sending chains T in X to X as $f(T) = c_T \notin T$. Such a function f exists by the axiom of choice. A subset $A \subseteq X$ is called a *conforming subset* if A is well-ordered, with respect to order on X , and for all $x \in A$, $f(I(A, x)) = x$. We claim that if A and B are conforming subsets of X , then $A = B$ or one is the initial segment of the other. For now, let us take this claim to be true. We shall prove it later.

If $f(\emptyset) = x$ then $A = \{x\}$. Note that A is conforming. But $I(A, x) = \emptyset \implies f(I(A, x)) = x$. Let U be the union of all conforming subsets of X . Then U is conforming since if $x \in U$ then $x \in B$ for some B conforming and $x = f(I(B, x)) = f(I(U, x))$. Let $f(U) = w$. Define a new set $\tilde{U} = U \sqcup \{w\}$, which is well-ordered and conforming. Then $U = I(\tilde{U}, w)$, which is a contradiction.

Coming back to the claim, suppose $x \in A \setminus B$. We wish to show that $B = I(A, x)$ for some $x \in A$. Let $x = \min(A \setminus B)$. We claim that this x works. $I(A, x) \subseteq B$ holds since if $y \in A$ and $y < x$ then $y \in B$, or else $x \neq \min(A \setminus B)$. Suppose, now, that the equality does not hold. Take $y = \min(B \setminus I(A, x))$ and $z = \min(A \setminus I(B, y))$. We claim that $I(A, z) = I(B, y)$. Take $v \in I(A, z)$; then $v < z$ implies $v \in I(B, y)$ since $z = \min(A \setminus I(B, y))$. Taking $u \in I(B, y)$, we have $u \in I(A, x) \implies u < x$ since $y = \min(B \setminus I(A, x))$. If $z \leq u$, then $z \in I(A, x) \subseteq B \implies z \in I(B, y)$ contradicting the fact that $z = \min(A \setminus I(B, y))$. Thus, $z > u$ and $y \in I(A, z)$. Finally, $z = f(I(A, z)) = f(I(B, y)) = y$ implies $z = x = y$. But this is a contradiction since $x \in A \setminus B$ and $y \in B$. ■

Definition 1.17. A relation R on a set A is said to be an *equivalence relation* if it is reflexive, symmetric, and transitive. Let $x \in A$. Then $[x] = \{yRx \mid y \in A\} \subseteq A$ is called the *equivalence class* of x .

We note that $\bigcup_{x \in A} [x] = A$ and for $x, y \in A$, either $[x] \cap [y] = \emptyset$ or $[x] = [y]$. Thus, we get a partition of A into equivalence classes.

Let I be an indexing set, and let A_i be sets for all $i \in I$. Then the existence of $X_{i \in I} A_i = \{f : I \rightarrow \bigcup A_i \mid f(i) \in A_i \text{ for all } i \in I\}$ is another way of stating the axiom of choice.

Theorem 1.18 (The *principle of induction*). Let $S(n)$ be statements about the naturals $n \in \mathbb{N}$. Suppose $S(1)$ holds and for all $k \in \mathbb{N}$, $S(k) \implies S(k+1)$. Then $S(n)$ holds true for all $n \in \mathbb{N}$.

Let I be a well-ordered set and let $S(i)$ be statements for all $i \in I$. Suppose that if $S(j)$ holds for all $j < i$, then $S(i)$ holds. Then $S(i)$ holds for all $i \in I$. This is the *principle of transfinite induction*, which is also equivalent to the axiom of choice. We now properly introduce the theory of groups.

1.2 Groups

We first define a group.

Definition 1.19. A *group* is a triple (G, \cdot, e) where G is a set, $\cdot : G \times G \rightarrow G$ is a binary operation on G , and $e \in G$ is an element of G satisfying the following axioms:

- The property of *associativity*: For $a, b, c \in G$, $(a \cdot b) \cdot c = a \cdot (b \cdot c)$.
- The property of the *identity element*: For all $a \in G$, $a \cdot e = e \cdot a = a$. e is referred to as the identity element.
- The existence and property of the *inverse element*: For all $a \in G$, there exists $b \in G$ such that $a \cdot b = b \cdot a = e$.

In addition, (G, \cdot, e) is also termed an *abelian group* if for all $a, b \in G$, $a \cdot b = b \cdot a$, that is, commutativity holds.

A group may also be rewritten as (G, \cdot) , or just G . Some examples include $(\mathbb{Z}, +)$, $(\mathbb{Q}, +)$, $(\mathbb{R}, +)$, $(\mathbb{C}, +)$. The set (\mathbb{Q}, \cdot) is not a group since 0 does not have an inverse. However, (\mathbb{Q}^*, \cdot) is a group, where $\mathbb{Q}^* = \mathbb{Q} \setminus \{0\}$. All these groups are also abelian. An example of a non-abelian group is S_n , the set of all bijections from $\{1, 2, \dots, n\}$ to itself, under the binary operation of composition of functions. Another non-abelian group is $(GL_n(\mathbb{R}), \cdot)$, for $n \geq 2$, the set of all invertible real $n \times n$ matrices.

July 24th.

From the axioms, arise basic properties related to groups.

Proposition 1.20. Let (G, \cdot, e) be a group.

1. Let $a \in G$ be such that $a \cdot b = b$ for all $b \in G$. Then $a = e$; the identity element is unique.
2. Each element $a \in G$ has a unique inverse. Thus, the inverse of a is then termed a^{-1} .
3. $(a^{-1})^{-1} = a$ holds for all $a \in G$.
4. For all $a, b \in G$, $(a \cdot b)^{-1} = b^{-1} \cdot a^{-1}$.
5. Let $a \in G$ be such that $a \cdot b = b$ for some $b \in G$. Then $a = e$.

Proof. 1. Choose b to be e . Then $a \cdot e = e$ by hypothesis, and $a \cdot e = a$ by the property of the identity element. Thus, $a = e$.

2. Let $a \in G$ and $b \in G$ be such that $a \cdot b = b \cdot a = e$. Let $c \in G$ be also such that $c \cdot a = e$. Thus, $(c \cdot a) \cdot b = e \cdot b \Rightarrow c \cdot (a \cdot b) = e \cdot b \Rightarrow c \cdot e = b \Rightarrow c = b$.

3. Easy to see since $a^{-1} \cdot a = a \cdot a^{-1} = e$ which just means that the inverse of a^{-1} is a .

4. Also easy since $(a \cdot b) \cdot (b^{-1} \cdot a^{-1}) = (b^{-1} \cdot a^{-1}) \cdot (a \cdot b) = e$.

5. Finally, right multiplying b^{-1} leads to $a = a \cdot b \cdot b^{-1} = b \cdot b^{-1} = e$. ■

July 29th.

Definition 1.21. The *order* of a group G is the cardinality of the set G , and is denoted by $|G|$, $o(G)$, or $\text{ord}(G)$. If $|G|$ is finite, we say G is a *finite group*.

We provide some examples.

Example 1.22. • The *trivial group* is $G = \{e\}$, with $e \cdot e = e$. Here, $|G| = 1$, and it is the smallest possible finite group. Similarly, one can form a group with two elements as $G = \{e, a\}$, with $a \cdot a = e$ and $a \cdot e = e \cdot a = a$.

- Another important example is the set of all bijections of a set X , denoted by $S(X)$. It forms a group under composition. Here, if $f, g \in S(X)$, then $f \circ g \in S(X)$. Similarly, the bijection $\text{id}_X(x) = x$ for all $x \in X$ is the identity element of $S(X)$. Associativity also holds, and the inverse of $f \in S(X)$ is simply the inverse mapping $f^{-1} \in S(X)$ to get $f \circ f^{-1} = f^{-1} \circ f = \text{id}_X$. If $X = \{1, 2, \dots, n\}$, then $S(X)$ is also denoted by S_n , with $|S_n| = n!$. If the set X is infinite, then so is $S(X)$.
- The set $\mathbb{Z}/n\mathbb{Z}$ is a group when equipped with the binary operation of addition (+). Here, $|\mathbb{Z}/n\mathbb{Z}| = n$.
- The set $\mu_n = \{e^{2\pi im/n} \mid 1 \leq m \leq n\}$ is a group with respect to multiplication. Again, $|\mu_n| = n$.

Order is also defined for elements.

Definition 1.23. Let (G, \cdot, e) be a group. The *order of an element* $a \in G$, denoted $o(a)$, $\text{ord}(a)$, or $|a|$, is the least $n \geq 1$ such that $a^n = e$. If no such n exists, then we term $|a| = \infty$.

Examples follow.

Example 1.24. • In μ_n , $o(e^{2\pi i/n}) = n$.

- Similarly, in $\mathbb{Z}/n\mathbb{Z}$, $o([1]_n) = n$. For a general element $[a]_n \in \mathbb{Z}/n\mathbb{Z}$, the order is $o([a]_n) = \frac{n}{\gcd(a, n)}$.

Proposition 1.25. Let G be a finite group. For all $a \in G$, $o(a)$ is finite.

Proof. Let $a \in G$. We look at $a, a^2, a^3, \dots \in G$. Since G is finite, not all are distinct; there exists $m > n$ such that $a^m = a^n$. Multiplying by a^{-n} , we have $a^{m-n} = a^{n-n} = e$, and the order of a is finite. ■

1.2.1 The S_n Group

To understand the order better, we look specifically at S_3 .

Example 1.26. The elements in S_3 are

$$\begin{pmatrix} 1 & 2 & 3 \\ 1 & 2 & 3 \end{pmatrix}, \begin{pmatrix} 1 & 2 & 3 \\ 2 & 1 & 3 \end{pmatrix}, \begin{pmatrix} 1 & 2 & 3 \\ 1 & 3 & 2 \end{pmatrix}, \begin{pmatrix} 1 & 2 & 3 \\ 3 & 2 & 1 \end{pmatrix}, \begin{pmatrix} 1 & 2 & 3 \\ 2 & 3 & 1 \end{pmatrix}, \text{ and } \begin{pmatrix} 1 & 2 & 3 \\ 3 & 1 & 2 \end{pmatrix}. \quad (1.3)$$

Alternatively, the elements may be (correspondingly) written as

$$e, (1 \ 2), (2 \ 3), (1 \ 3), (1 \ 2 \ 3), \text{ and } (3 \ 2 \ 1). \quad (1.4)$$

It is easy to see that the orders of $e, (1 \ 2), (1 \ 2 \ 3)$ are 1, 2, 3, respectively. The elements $(1 \ 2), (2 \ 3)$, and $(1 \ 3)$ are termed *transpositions*. In general, an element $\sigma \in S_n$ is called a *transposition* if there exists $1 \leq a \neq b \leq n$ such that $\sigma(a) = b$ and $\sigma(b) = a$, but $\sigma(x) = x$ for all $x \notin \{a, b\}$.

An element $\sigma \in S_n$ is called a *cycle* if there exists distinct $1 \leq a_1, a_2, \dots, a_m \leq n$ such that $\sigma(a_i) = a_{i+1}$ for $1 \leq i \leq m-1$, $\sigma(a_m) = a_1$, and $\sigma(x) = x$ for all $x \notin \{a_1, a_2, \dots, a_m\}$. Thus, a transposition is really just a cycle of length 2. If σ is a cycle of length m , then $o(\sigma) = m$.

In the above, $\sigma^i(a_1) = a_{i+1}$ if $i < m$. Thus, $\sigma^i \neq e$ for $i < m$. But for m -times composition, we have $\sigma^m(a_i) = a_i$ for all $1 \leq i \leq m$. Hence, the order of σ is really m .

Note that S_3 is non-abelian since $(1 \ 2)(1 \ 3) = (1 \ 3 \ 2)$, but $(1 \ 3)(1 \ 2) = (1 \ 2 \ 3)$.

Definition 1.27. Let $\sigma, \tau \in S_n$ be cycles. They are called *disjoint cycles* if $\sigma = (a_1, \dots, a_m)$ and $\tau = (b_1, \dots, b_k)$, and $\{a_1, \dots, a_m\} \cap \{b_1, \dots, b_k\} = \emptyset$.

If σ and τ are disjoint cycles then they commute; that is, $\sigma \circ \tau = \tau \circ \sigma$.

Proposition 1.28. *Every element of S_n can be written as a product of disjoint cycles.*

Proof. Let $\sigma \in S_n$, and let k be the least positive integer such that $\sigma^k(1) = 1$. Then let $\tau_1 = (1 \ \sigma(1) \ \sigma^2(1) \ \dots \ \sigma^{k-1}(1))$. Let S'_1 be the *support* of τ_1 , defined as $\text{supp}(\tau_1) = \{1, \sigma(1), \dots, \sigma^{k-1}(1)\}$. If $S'_1 = \{1, 2, \dots, n\}$, we are done. Otherwise, let $a_2 = \min(\{1, 2, \dots, n\} \setminus S'_1)$. Let k_2 be the least positive integer such that $\sigma^{k_2}(a_2) = a_2$, and then let $\tau_2 = (a_2 \ \sigma(a_2) \ \dots \ \sigma^{k_2-1}(a_2))$. Then τ_2 is a cycle of length of k_2 . Again, let $S'_2 = \text{supp}(\tau_2)$. We claim that $S'_1 \cap S'_2 = \emptyset$.

If $\sigma(a_2)$ were in S'_1 , then we would have $\sigma^i(i) = a_2 \in S'_1$, but a_2 was taken from $\{1, 2, \dots, n\} \setminus S'_1$. Similarly, if $\sigma^j(a_2) \in S'_1$, then a similar problem arises. Thus, the sets have to be disjoint.

Continue this way to get $\tau_1, \tau_2, \dots, \tau_l$ until $S'_1 \cup S'_2 \cup \dots \cup S'_k = \{1, 2, \dots, n\}$. The process stops since S'_1, S'_2, \dots, S'_k are non-empty. Thus, we conclude that $\tau_1 \circ \tau_2 \circ \dots \circ \tau_l$ is the disjoint cycle decomposition of σ . ■

For ease of notation, we will write $\sigma \circ \tau$ as $\sigma\tau$.

Proposition 1.29. *Let $\sigma \in S_n$ and $\sigma = \tau_1\tau_2 \cdots \tau_k$ be a disjoint cycle decomposition of σ . Then, $|\sigma| = \text{lcm}(|\tau_1|, |\tau_2|, \dots, |\tau_k|)$.*

Proof. The proof of this proposition is left as an exercise to the reader. ■

1.3 Subgroups

We begin with the definition.

Definition 1.30. A non-empty subset H of a group (G, \cdot) is called a *subgroup* if the following properties hold.

1. For all $a, b \in H$, $a \cdot b \in H$.
2. For all $a \in H$, $a^{-1} \in H$.

In such a scenario, we write $H \leq G$.

More properties of a subgroup can be inferred.

Proposition 1.31. *The following properties hold true for a subgroup $H \leq G$, where (G, \cdot, e) is a group.*

1. $e \in G$.
2. (H, \cdot, e) is a group.

Proof. 1. H is non-empty, so there exists $a \in G$ such that $a \in H$. From the definition, $a^{-1} \in H$ also. Since H is closed under the binary operation, we have $a \cdot a^{-1} = e \in H$.

2. We show that (H, \cdot, e) satisfies the group axioms. From definition, \cdot is an associative binary operation on H . Also, e is the identity element in H . Again, from the definition, each $a \in H$ has an inverse $a^{-1} \in H$. ■

Equivalently, H is a subgroup if the following holds.

Theorem 1.32. *Let G be a group and $H \subseteq G$ be non-empty. Then H is a subgroup of G if and only if $a \cdot b^{-1} \in H$ for all $a, b \in H$.*

Proof. The forward implication is left as an exercise to the reader. If $a \in H$ then $a \cdot a^{-1} \in H$ shows that $e \in H$. Since $e, a \in H$, $e \cdot a^{-1} = a^{-1} \in H$. If $a, b \in H$, then $a, b^{-1} \in H \implies a \cdot (b^{-1})^{-1} \in H \implies ab \in H$ ■

July 31st.

We look at some examples of subgroups.

Example 1.33. • For any group G , $\{e\} \subseteq G$ is a subgroup. This is termed the *trivial group*.

- Any group G is a subgroup of itself.
- We have $(\mathbb{Z}, +) \leq (\mathbb{Q}, +) \leq (\mathbb{R}, +) \leq (\mathbb{C}, +)$. Similarly, $(\{\pm 1\}, \cdot) \leq (\mathbb{Q}^*, \cdot) \leq (\mathbb{R}^*, \cdot) \leq (\mathbb{C}^*, \cdot)$.
- If $H \leq G$ and $K \leq H$, then $K \leq G$.
- $\mu_n \leq (\mathbb{C}^*, \cdot)$ for all natural n .
- For $(\mathbb{Z}/6\mathbb{Z}, +) = \{\bar{0}, \bar{1}, \bar{2}, \bar{3}, \bar{4}, \bar{5}\}$, the only possible subgroups are $\{\bar{0}\}$, $\{\bar{0}, \bar{3}\}$, $\{\bar{0}, \bar{2}, \bar{4}\}$, and $\{\bar{0}, \bar{1}, \bar{2}, \bar{3}, \bar{4}, \bar{5}\}$.

1.3.1 Generation

Definition 1.34. Let G be a group and $S \subseteq G$ be a subset. We say S generates a subgroup H if H is the smallest subgroup of G containing S . We denote this as $\langle S \rangle = H$.

Remark 1.35. Let $H_1, H_2 \leq G$. Then $H_1 \cap H_2 \leq G$.

Proof. Note that $e \in H_1, H_2$, so $H_1 \cap H_2 \neq \emptyset$. Also, if $x, y \in H_1 \cap H_2$, then $xy^{-1} \in H_1 \cap H_2$. We are done. ■

Proposition 1.36. For $S \subseteq G$, $\langle S \rangle$ always exists and is unique.

Proof. Let $\Omega = \{H \leq G \mid S \subseteq H\}$. Since $G \in \Omega$, it is non-empty. Thus, we simply take $\langle S \rangle = \bigcap_{H \in \Omega} H$, which is the smallest subgroup containing S . ■

The above proof is merely of existence, and will be a hassle for constructing the generated group. The following proposition simplifies the construction process.

Proposition 1.37. Let G be a group and $S \subseteq G$ be a subset. Then

$$\langle S \rangle = H = \{a_1 \cdots a_n \mid a_i \in S \text{ or } a_i^{-1} \in S \text{ for } n \geq 1\} \cup \{e\}. \quad (1.5)$$

Proof. Note that $S \subseteq H$, so H is non-empty. Let $x, y \in H$. Then, $x = a_1 \cdots a_n$ with $a_i \in S$ or $a_i^{-1} \in S$. Similarly, $y = b_1 \cdots b_m$ with $b_j \in S$ or $b_j^{-1} \in S$. We then have

$$a_1 \cdots a_n b_m^{-1} \cdots b_1^{-1} \text{ with } a_i \in S \text{ or } a_i^{-1} \in S, \text{ and } (b_j^{-1})^{-1} \in S \text{ or } b_j^{-1} \in S. \quad (1.6)$$

Thus, $xy^{-1} \in H$ and $\langle S \rangle \subseteq H$. For the converse inclusion, it is enough to show that if H' is a subgroup such that $S \subseteq H'$, then $H \leq H'$. Suppose H' is such a subgroup. Then $a_1 \cdots a_n \in H'^{-1}$ for $a_i \in S$ or $a_i^{-1} \in S$ since $a_i \in S \subseteq H' \implies a_i^{-1} \in H'$ and $x, y \in H' \implies xy \in H'$. Hence, $H \leq H'$. ■

Definition 1.38. A group G is termed a *cyclic group* if there exists $a \in G$ such that $\langle \{a\} \rangle = G$. Usually, we prefer to write it as $\langle a \rangle = G$.

Example 1.39. $\mathbb{Z}/n\mathbb{Z} = \langle \bar{1} \rangle$ for all natural n .

Proposition 1.40. *The group S_n is generated by transpositions, for all $n \geq 1$.*

Proof. From **Proposition 1.28**, every $\sigma \in S_n$ can be written as $\sigma = \tau_1 \cdots \tau_k$ where $\tau_i \in S_n$ are cycles. So it is enough to show that every cycle is a product of transpositions. Suppose $(i_1 \ i_2 \ \cdots \ i_l)$ is such a cycle with i_1, \dots, i_l being distinct elements of $\{1, 2, \dots, n\}$. This can be rewritten simply as

$$(i_1 \ i_2 \ \cdots \ i_l) = (i_1 \ i_l)(i_1 \ i_{l-1}) \cdots (i_1 \ i_3)(i_1 \ i_2). \quad (1.7)$$

■

Example 1.41. Let us look at $S_3 = \{e, (1 \ 2), (2 \ 3), (1 \ 3), (1 \ 2 \ 3), (3 \ 2 \ 1)\}$. Then the only possible subgroups are

- $\{e\}$,
- $\{e, (1 \ 2)\}$,
- $\{e, (2 \ 3)\}$,
- $\{e, (1 \ 3)\}$,
- $\{e, (1 \ 2 \ 3), (3 \ 2 \ 1)\}$, and
- S_3 .

An important subgroup of S_n is A_n , defined as the set of all permutations in S_n with even parity; all permutations that can be written as the product of even number of transpositions. A_n is termed the *alternating group*. Similarly, D_n is also defined. The *dihedral group* D_n is the group of symmetries of a n -regular polygon, which includes rotations and reflections. Labelling the vertices as 1 through n , the rotations and reflections can really be seen as those permutations in S_n that leave the n -regular polygon as itself after permutation. For example, D_4 is the group $\{\sigma \in S_4 \mid \sigma(\square) \text{ is still a } \square\}$. If n is even, we can write

$$D_n = \langle (1 \ 2 \ \cdots \ n), (1 \ n)(2 \ n-1) \cdots (\frac{n}{2} \ \frac{n}{2} + 1) \rangle. \quad (1.8)$$

If n is odd, we have

$$D_n = \langle (1 \ 2 \ \cdots \ n), (1 \ n-1)(2 \ n-2) \cdots (\frac{n-1}{2} \ \frac{n+1}{2}) \rangle. \quad (1.9)$$

Chapter 2

COSETS AND MORPHISMS

2.1 Cosets

We start with cosets.

Definition 2.1. Let $H \leq G$ and $x \in G$. A *left coset* of H generated by x is $xH = \{xh \mid h \in H\} \subseteq G$. The left coset need not be a subgroup of G . Similarly, a *right coset* of H generated by x is $Hx = \{hx \mid h \in H\} \subseteq G$. Again, the right coset need not be a subgroup

Let $H \leq G$. For $x, y \in G$, let us write $x \sim y$ if $x^{-1}y \in H$. Then \sim is an equivalence relation. Moreover, $[x] = xH$ for all $x \in G$. Once we have proved, we will be able to partition our group.

Proof. Clearly, \sim is reflexive since $x^{-1}x = e \in H$ for all $x \in G$. \sim is symmetric since we have

$$x \sim y \implies x^{-1}y \in H \implies (x^{-1}y)^{-1}H \implies y^{-1}x \in H \implies y \sim x. \quad (2.1)$$

Finally, \sim is also transitive since

$$x \sim y \text{ and } y \sim z \implies x^{-1}y, y^{-1}z \in H \implies x^{-1}y \cdot y^{-1}z = x^{-1}z \in H \implies x \sim z. \quad (2.2)$$

To show the latter result, we first have

$$y \in [x] \implies x \sim y \implies x^{-1}y \in H \implies xx^{-1}y = y \in xH \implies y \in xH. \quad (2.3)$$

So, $[x] \subseteq xH$. For the converse inclusion, we have

$$y \in xH \implies y = xh \text{ for some } h \in H \implies x^{-1}y = h \in H \implies y \in [x]. \quad (2.4)$$

Thus, $xH \subseteq [x]$ and $xH = [x]$. ■

The above results of cosets prove to be useful in the following theorem.

Theorem 2.2 (*Lagrange's theorem*). Let G be a finite group with $H \leq G$. Then $|H| \mid |G|$.

Proof. For $x, y \in G$, if $xH \cap yH \neq \emptyset$, then we must have $xH = yH$. Also, $\bigcup_{x \in G} xH = G$. We now claim that $|xH| = |yH|$ for all $x, y \in G$. To show this, we let $f : xH \rightarrow yH$ be defined as $f(a) = yx^{-1}a$, and $g : yH \rightarrow xH$ be defined as $g(b) = xy^{-1}b$. Then f and g are inverses of each other since

$$(f \circ g)(b) = f(xy^{-1}b) = yx^{-1}xy^{-1}b = b \text{ and } (g \circ f)(a) = g(yx^{-1}a) = xy^{-1}yx^{-1}a = a. \quad (2.5)$$

Let $S = G / \sim$ (also denoted as G/H). Since $G = \bigcup_{A \in S} A$, we have $|A| = |H|$ for all $A \in S$, implying $|G| = |S||H|$. ■

Corollary 2.3. *Let G be a finite group, with $a \in G$. Then $o(a) \mid |G|$.*

Proof. If $o(a) = n$, then $\langle a \rangle = \{a, a^2, \dots, a^{n-1}, e\}$. Since this is a subgroup, we have $|\langle a \rangle| = n \mid |G|$ by Lagrange's theorem. ■

2.2 Mappings

August 5th.

We now study important mappings between groups and the types of mappings one can define.

Definition 2.4. A function $f : (G, *) \rightarrow (H, \circ)$, where $(G, *)$ and (H, \circ) are groups, is said to be a (group) *homomorphism* if

$$f(x * y) = f(x) \circ f(y) \text{ for all } x, y \in G. \quad (2.6)$$

The following is a trivial example of a group homomorphism.

Example 2.5. For instance, the map $a \mapsto a$ in $(\mathbb{Z}, +) \rightarrow (\mathbb{Q}, +)$ is a group homomorphism, trivially. More generally, if $H \leq G$, then $a \mapsto a$, called the *inclusion map* is a group homomorphism.

Homomorphisms can be classified further if they inherit nicer properties.

Definition 2.6. The group homomorphism is also called an injective homomorphism, or a *monomorphism*, if the mapping is also injective. Similarly, it is also called a surjective homomorphism, or a *epimorphism*, if the mapping is also surjective. Finally, the group homomorphism is termed an *isomorphism* if it is bijective.

- Example 2.7.**
1. The map $q : (\mathbb{Z}, +) \rightarrow (\mathbb{Z}/n\mathbb{Z}, +)$ defined as $q(a) = [a]_n$ for $n \geq 1$ is a group homomorphism. Specifically, it is an epimorphism.
 2. $f : (G, *) \rightarrow (\{e\}, \cdot)$ with $f(g) = e$ for all $g \in G$ is another epimorphism. This is also a trivial homomorphism.
 3. The scaling map $a \mapsto \lambda a$ in $\mathbb{Z} \rightarrow \mathbb{Z}$ is a monomorphism for $\lambda \in \mathbb{Z}_{\geq 1}$. Similarly, $[a] \mapsto [\lambda a]$ in $\mathbb{Z}/n\mathbb{Z} \rightarrow \mathbb{Z}/n\mathbb{Z}$ is group homomorphism. If $\gcd(n, \lambda) = 1$, then the map is also an isomorphism in this case.
 4. The scaling map $f : \mathbb{Q} \rightarrow \mathbb{Q}$ with $f(a) = ca$ with $c \in \mathbb{Q}^*$ is an isomorphism. For $c = 0$, we get the trivial homomorphism.
 5. From linear algebra, the map $T : (\mathbb{Q}^n, +) \rightarrow (\mathbb{Q}^n, +)$ with $T \in M_n(\mathbb{Q})$ defined as $v \mapsto Tv$ is also a group homomorphism. If $T \in GL_n(\mathbb{Q}) \subseteq M_n(\mathbb{Q})$, the map is also an isomorphism.
 6. Towards more non-trivial examples, one can confirm that the map $\exp : (\mathbb{R}, +) \rightarrow (\mathbb{R}_{>0}, \cdot)$ defined as $x \mapsto e^x$ is a group homomorphism.

2.2.1 Properties

Arising from these structure-preserving mappings are some useful properties.

Proposition 2.8. *Let $f : (G, *) \rightarrow (H, \circ)$ be a group homomorphism. Then*

1. $f(e_G) = e_H$,
2. $f(a^n) = f(a)^n$, and
3. $f(a)^{-1} = f(a^{-1})$.

Proof. 1. Simply work as

$$f(e_G) = f(e_G * e_G) = f(e_G) \circ f(e_G) \implies e_H = f(e_G)^{-1} \circ f(e_G) = f_{e_G}. \quad (2.7)$$

2. We show the base case, then induction may be applied.

$$f(a^2) = f(a * a) = f(a) \circ f(a) = f(a)^2. \quad (2.8)$$

3. Again,

$$f(a^{-1}) \circ f(a) = f(a^{-1} * a) = f(e_G) = e_H = f(a)^{-1} \circ f(a) \implies f(a^{-1}) = f(a)^{-1}. \quad (2.9)$$

■

We show further some properties of bijective homomorphisms.

Proposition 2.9. *Let $f : (G, *) \rightarrow (H, \cdot)$ be a group isomorphism. Then*

1. $f^{-1} : H \rightarrow G$ is a group isomorphism,
2. $o(x) = o(f(x))$ for all $x \in G$,
3. $|G| = |H|$, and
4. G is abelian if and only if H is abelian.

Proof. 1. Fix $a, b \in H$, and let $x = f^{-1}(a)$ and $y = f^{-1}(b)$. We want to show that $f^{-1}(a \cdot b) = f^{-1}(a) * f^{-1}(b)$. To this end, we have

$$f(f^{-1}(a) * f^{-1}(b)) = f(x * y) \Rightarrow f(f^{-1}(a)) \cdot f(f^{-1}(b)) = a \cdot b = f(x * y) \Rightarrow f^{-1}(a \cdot b) = x * y. \quad (2.10)$$

2. Let $o(x) = n$, where $x^m \neq e_G$ for $1 \leq m < n$ and $x^n = e_G$. This shows that $f(x)^n = f(x^n) = e_H$. Also, since $x^m \neq e_G$ for $1 \leq m < n$, we must have $f(x^m) \neq e_H$ for $1 \leq m < n$ as f is bijective. Thus, $o(f(x)) = o(x)$. If $o(x)$ were not finite, then $x^n \neq e_G$ for all $n \geq 1$ implies $f(x)^n \neq e_H$ for all $n \geq 1$.

3. This is trivial.

4. If G is abelian then $a * b = b * a$ for all $a, b \in G$. Applying f , we get $f(a * b) = f(b * a) \Rightarrow f(a) \cdot f(b) = f(b) \cdot f(a)$ for all $a, b \in G$. If we take $a = f^{-1}(x)$ and $b = f^{-1}(y)$, we get $x \cdot y = y \cdot x$ for all $x, y \in H$. For the converse implication, simply consider the isomorphism f^{-1} .

■

Essentially, in group theory, we consider two groups the same if they are isomorphic. Thus, we are equipped to classify groups up to isomorphism seeing as they share basically the same structure and properties. If two groups G and H are isomorphic, we denote it as $G \cong H$.

Proposition 2.10. *Let (G, \cdot) be a group of order p , where p is prime. Then $G \cong \mathbb{Z}/p\mathbb{Z}$.*

Proof. Let $x \in G$ be a non-identity element. Then $o(x) = p$ since $o(x) \mid p$ and $o(x) \neq 1$. Define the map $f : \mathbb{Z}/p\mathbb{Z} \rightarrow G$ as $f(a) = x^a$. We show that this mapping is an isomorphism. For $\bar{a}, \bar{b} \in \mathbb{Z}/p\mathbb{Z}$, we have

$$f(\bar{a} + \bar{b}) = f(\overline{a+b}) = x^{a+b} = x^a \cdot x^b = f(\bar{a}) \cdot f(\bar{b}) \quad (2.11)$$

showing f is a group homomorphism. Moreover, $G = \langle x \rangle$ as $o(x) = p$, so G is also surjective. Hence, f is an isomorphism as G is finite.

■

Example 2.11. We find all the groups of order 4 upto isomorphism. The only two possibilities are $\mathbb{Z}/4\mathbb{Z}$, and $(\mathbb{Z}/2\mathbb{Z})^2$ with component-wise addition.

Example 2.12. We list down all the groups of order 6 upto isomorphism. Again, the only two possibilities are $\mathbb{Z}/6\mathbb{Z}$ and S_3 .

Example 2.13. For groups of order 8, we have $\mathbb{Z}/8\mathbb{Z}$, $(\mathbb{Z}/2\mathbb{Z})^2$, $\mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z}$, D_4 , and \mathbb{Q}_8 , the *quaternions*.
